W81XWH-11-1-0682

TITLE:  
MALDI/Mass Spectrometry of "Normal Appearing" and Dystrophic Axons in Spinal Cord of Multiple Sclerosis (MS)

PRINCIPAL INVESTIGATOR:  
Dr. Subramaniam Sriram

CONTRACTING ORGANIZATION:  
Vanderbilt University  
Nashville, TN 37240-0001

REPORT DATE:  
September 2013

TYPE OF REPORT:  
Final

PREPARED FOR: U.S. Army Medical Research and Materiel Command  
Fort Detrick, Maryland 21702-5012

DISTRIBUTION STATEMENT:

Approved for public release; distribution unlimited

<b>14. ABSTRACT</b> Multiple sclerosis is often considered to be disease affecting the insulating material around the nerves, also referred to as myelin, which is caused by an abnormal immune response to proteins in the insulating sheath surrounding nerves. More recent studies have suggested that in addition to myelin the nerve fibers are also destroyed in MS. In fact the major cause of disability in MS is most likely due to damage to the nerves. The abnormalities in the nerves are most prominent in the spinal cord. At present there is little or no information on the causes for the destruction of the nerves in the spinal cord. Using state of the art techniques our study will examine the changes in the nerves in spinal cord of patients who have died from progressive MS. We will dissect out the abnormal regions of the spinal cord subject and determine the changes in the nerves in MS patients compared with patients who have died from other causes. We predict that we will be able to show the nature of the abnormality in the nerves of MS patients. These studies are likely to point to novel mechanism that can protect the nerves and restore neurological function.

## Progress Report:

Introduction: The design of the study was to define the protein signature of dystrophic and non dystrophic axons in corticospinal tracts of spinal cord of MS patients using laser capture microdissection and MALDI-Mass Spectrometry. Halting the progression of MS is of utmost urgency today. While therapies that decrease the number and severity of relapses are currently available, none of the current therapies alter the progression of MS. Once progressive disease is manifest, most patients show an inexorable worsening of gait, balance and autonomic function. Understanding the nature of the progression is of utmost importance in devising new and novel therapies in MS.

Objective: Using MALDI/mass spectrometry we will determine:

- (a) if "normal appearing" large diameter axons in CS tracts of MS patients differ from those seen in controls?
- (b) the protein profile of dystrophic small axons in CS tracts differ when compared with normal large axons and those of non MS controls?

Progress: We have collected 6 spinal cords from patients who had died from complications of secondary progressive MS. The spinal cord tissue was obtained from the Brain Bank in the Netherlands. Multiple sections of the spinal cord tissue were taken and stained for myelin and axons. In all the 6 MS spinal cords areas of demyelination and normal appearing white matter were obtained.

Axonal staining was done and we have identified regions of the white matter with a larger sized axons and those with smaller size axons. Our first experiment was designed to examine the white matter areas using MADLI/spectroscopy between MS and healthy controls. We have subjected the following regions of white matter from MS and controls for MADLI: a) normal appearing white matter areas with large axons in MS and healthy controls, b) normal appearing white matter with smaller density of axons between normal and MS patients, c) demyelinated regions of white matter in MS patients. The data set from the different regions has been pre-processed and are currently being analysed.

Potential problems: We faced two main problems in our study and these were delays that were not in our control.

1. We were delayed in the start of the experiments by about 4 months in the acquisition of the tissue material for study. The tissues were obtained from outside of the US and the regulatory issues involved.
2. The MALDI/spectroscopy machine malfunctioned from April 2012 to June 2012. For these reasons there was a back log of tissues which could not be processed and there was a delay in getting our experiments done in a timely manner.

## Research accomplishments:

- a) Histochemical and immune-histological analysis of regions of normal and abnormal appearing axons in spinal cord of MS patients and controls
- b) MALDI/spectrometric analysis of these regions and preliminary determination of the differences in regions of normal appearing white matter between MS and controls.

We had six spinal cords from patients with MS and another five from control.

In MALDI experiment, from each section of the spinal cord, at least two areas were collected from the spinal cord of MS patients: one was from demyelination area and the other from NAWM (post-column). The corresponding areas from the spinal cord of control individuals were collected as well.

The following areas were subjected to MALDI analysis:

1. The samples from the areas of demyelination in MS vs. corresponding areas non-demyelinated in control.
2. The samples from the areas of demyelination in MS vs. the areas of NAWM in MS, both from post column.
3. The samples from the areas of NAWM in MS vs. corresponding normal appearing white matter in the controls, both from post column.

When we compared areas of demyelination in MS versus corresponding areas which were non demyelinated in controls we were able to identify 262 spectral peaks which were different in MS from that seen in controls (Table 1).

In the second analysis of normal appearing white matter and demyelinated areas in MS spinal cord we identified 262 spectral peaks which differed from regions of demyelination in MS when compared to controls (Table2).

In the final analysis when we compared normal appearing white matter between MS and controls 38 specific peaks were identified (Table 3).

Sequencing of peaks of high significance:

It was our strategy to first examine the 38 MZ peaks which were different in normal appearing white matter when compared to controls. We believed that these regions are likely to be most informative and provide protein abnormalities in regions of white matter of MS patients which show normal staining but yet have a spectral pattern which is different from that seen in controls. We have so far identified 8 spectral regions which show promise.

We have attempted analyze the peptide sequence of the 8 proteins which are different in MS from controls. After three attempts we have been unable to obtain reproducible results as to the identity of the peptides.

Reportable outcomes: None

Conclusions: Our preliminary studies have shown that there are differences in the MALDI/spectroscopy signature between the normal appearing regions of spinal cord from MS patients and healthy control. This is important and we were limited by the amount of tissue to clearly characterize the peptides of the lesions. We will require more tissue to clearly analyze the differences in the protein signature of the normal appearing white matter in MS patients with that seen in controls.
